Format of SOLOII X messages: Argo Version Manual/Decoder V2.1 latest update: 07 Dec 2016 [For ROM SBE602 19Aug15, 28Sep15, 11Dec15, 23Feb16,11May16]

An X message is used to transfer data from ISU to GS (ground station) or from GS to ISU. The data is assumed to be binary and each byte can have any value from 0x00 to 0xff. The format of the message is the same regardless of direction of transmission:

Xnnmmddp<data>\$cc>

- X = the character X
- nn = number of data characters in the message following after nn. The count does not include **X** ,nn, or anything from **\$** to the end **>**. The count is in 2 binary bytes with MSB first and LSB second.
- mm = serial number of SOLOII. The SN is in 2 binary bytes with MSB first and LSB second.
- the dive number in 2 binary bytes with MSB first and LSB second.
 Dive number begins at -1 for the start-up, increments to 0 for the test dive, increments +1 for all normal' (0xE2) dives.
- p = one-byte packet ID index, range 0 to 255. Used to identify multiple X messages within a dive cycle. The data for each dive cycle starts with p=0.
- - **\$** = a dollar sign delimitor at start of the checksum
 - cc = the 8 bit byte-wise checksum from \mathbf{X} to the byte preceding the $\mathbf{\$}$. The 8 bit sum is coded as 2 4bit nibbles. The binary value of a nibble is converted to a visible character by adding 0x30. Thus a value of 0x0 -> 0x30 = character '0', 0x1 -> 0x31 = '1', 0xe -> 0x3e = '>', and 0xf -> 0x3f = '?'.
 - > = a > delimitor at end of checksum which also serves as a prompt to GS that the ISU is done transmitting and that the GS may now transmit to ISU.

The remainder of this document describes the format of the <data> portion of the message sent from SOLOII to the ground station (**GS**). The format of commands from **GS** sent to SOLOII will be described in another document.

Highlights in document

Fields that are moved relative to the previous float version are highlighted in cyan New fields relative to the previous version are highlighted in yellow

NOTE: For firmware including and later than V1.5: An ice detection algorithm was introduced. However, for the float to be able to use the algorithm, the Seabird CTD must be a SBE41CP-V3.0C. SBE41CP-V3.0A, does not contain the necessary commands. Thus not all floats may have operational ice detection due to hardware.

NOTE: For floats with firmware 19Aug15, the float incorrectly reports itself as a V2.0 float in the Argo message;

NOTE: For V2.1 floats after and including firmware 30Sep15, the code is compatible with SBE 41CP+;

BUGS:

7/21/17: If the 2nd GPS does not successfully set the time, the time reset may be corrupted by an integral number of days. This will cause the 0x40 and 0x50 message times to be incorrect in the next cycle.

The <data> section contains information from multiple sensors. Data from successive sensors are separated by a semicolon (';' = 0x 3b); the final sensor is terminated by a ';' (immediately preceding the \$ delimitor).

IDjj<sensor_data>;

ID = one-byte sensor ID code.

jj = Number of bytes for this sensor. The count includes **ID**, jj, and the trailing ;. The count is in 2 binary bytes with MSB first and LSB second.

; = delimitor at the end of each sensor's data.

The **ID** byte is divided into two 4-bit nibbles. The MS nibble identifies the sensor and the second nibble specifies the message number for that sensor. For example, the ID for first Pressure message is 0x10, the second is 0x11, the third 0x12, etc. For a 1000 sample profile, there will be 6 messages for each of the pressure, salinity and temperature sensors.

Sensor	ID byte(hex)	
GPS	00	fix at end of first diagnostic dive at start of mission
GPS	01	fix at before leaving surface
GPS	02	fix at end of normal profiling acsent
GPS	03	fix following mission abort
GPS	05	fix during BITest
Pressure	1x	depths of CTD readings
Temperature	2x	depth series of temperature
Salinity	3x	depth series of salinity
Fall Rate	4x	series of time, depth during SOLO II downward profile
Rise Rate	5x	series of time,depth from drift depth to surface
Pump Series	6x	pressure,time, voltage,current,vacuum for each pump
High Resolution Pressure	9x	High Resolution Pressure [x=0-7]
High Resolution Temperature	ax	High Resolution Temperature [x=0-7]
High Resolution Salinity	bx	High Resolution Salinity [x=0-7]
Drift Profile Pressure	9x	Drift profile of Pressure [x=8-F]
Drift Profile Temperature	ax	Drift profile of Temperature [x=8-F]
Drift Profile Salinity	bx	Drift profile of Salinity [x=8-F]
Mission EEPROM	dx	ASCII dump of mission parameters in EEPROM
Engineering	e0	diagnostic data in first diagnostic dive
Engineering	e2	engineering data in normal profiling dive
Engineering	e3	engineering data following mission abort
Engineering	e5	engineering data BIT test pass
Engineering	e6	engineering data BIT test failure
Argo Data	f0	Mission parameter list
Test pattern	f1	ID reserved, format not yet defined

GPS data (ID=0x00, 0x01, 0x02, 0x03, 0x05)

The LS nibble of the ID indicates in what phase of the mission the fix was taken. The remainder of the data is the same for all mission phases. The length of GPS data is in bytes 1 and 2. GPS fix data starts in byte 3:

i ali illissioli	phases. The length of GP3 data is in bytes I and 2. GP3 lix data starts in byte
Byte	Contents
0	Mission phase:
	0 = 1st diagnostic dive at the start of a mission
	1 = beginning of normal dive cycle (just before leaving surface)
	2 = end of a normal dive cycle
	3 = following mission abort
	5 = during BITest
1-2	Number of bytes in the message, $24 = 0x18$ with the format as described here
3	0 if fix is invalid, +2 if longitude is East, -2 if longitude is West
4-7	Signed latitude degrees * 1e7
8-11	Signed longitude degrees * 1e7 range (+180 to -180 degrees)
12-13	GPS week
	(traditional GPS week =0 to 1023 in LS 10 bits; rollover fix in MS 6 bits)
14	GPS day of week, 0=Sunday, 6=Saturday
15	UTC hour
16	UTC minutes
17	Time to get fix = (seconds to get fix)/10, range 0 to $255 = 0$ to 2550 seconds
18	Number of satellites used in fix
19	Minimum signal level
20	Average signal level
21	Maximum signal level
22	10*Horiz. dilution of precision
23	; terminator (0x3B)

Pressure data (ID=0x1n)
Temperature data (ID=0x2n)
Salinity data (ID=0x3n)

Profile data from the pressure, temperature, and salinity sensors are all processed in the same way and the message format differs only in the ID code. The SeaBird CTD takes a profile as the SOLOII ascends and stores the values internally. When SOLOII reaches the surface, it takes the data from the CTD and block averages it in depth into **PRO_BINS** (= 1000) bins.

The size of depth bins can vary with depth. The averaging scheme is determined by 5 parameters: **BLOK**, **PB1**, **PB2**, **AV1**, and **AV2**. The smallest bin size is **BLOK** decibars. Bins 0 thru **PB1**-1 have a vertical extent of **BLOK** decibars. Bins **PB1** thru **PB2**-1 are **AV1*BLOK** decibars tall while bins **PB2** thru **PRO_BINS**-1 are **AV2*BLOK** decibars. In the special case that **PB1** >= **PRO_BINS**, then all of the bins are **BLOK** decibars in extent, and the values of **PB2**, **AV1**, and **AV2** are ignored.

There are two options for packing the Core (bin averaged) profile data. The packing used within the message data stream is indicated via first nibble of the jj variable (see below).

1. Difference Packing (Standard to versions previous to V2.0, Optional in V2.0)

The data series from all channels are processed in the same way and are synchronous with each other. Each depth series is broken into sub-blocks of 25 samples, and a first-differencing method is applied to each sub-block to reduce the number of bytes required to transmit the data. Because the data series will generally be longer than the 189 bytes available in a 9601 SBD message, it is divided into multiple messages. Each message has an integral number of sub-blocks in it. The final sub-block of the time series may have fewer than 25 samples in it. The data message looks like:

IDjj<sub-block 0><sub-block 1> . . . <sub-block m>;

ID = one-byte sensor ID code and index. The low order hex digit is the message index for this sensor. For example, the pressure messages would have ID's:10.11.12...

jj = Profile Packing Format (MS nibble)/Number of bytes for this message (LS 3 nibbles).

Profile Packing Format = 0 for Legacy Diff. (backwards compatible), 1 for Curv.

Number of bytes count includes ID, jj, the data, and the trailing;

<sub-block i> = first-differenced data from the ith sub=block where i=1,..,m =number of sub-blocks. If i<m, the sub-block will have 25 values in it and will have a total length of 22 bytes. The mth sub-block will have between 1 and 25 values and a length between 3 and 27 bytes.</p>

Suppose a sub-block has the n values v[0], v[1],...v[n-1]. Then this sub-block will be transmitted as:

Sub-block Byte	Contents
0	one-byte scaling factor S, range = 1 to 255. S is chosen so that the scaled first-differences fit in one byte, i.e. diff <= 127.
1	MS byte of v[0]
2	LS byte of v[0]
3	LS byte of { v[1] - v[0] }/S
4	LS byte of $\{v[2] - v[1]\}/S$
n+1	LS byte of { v[n-1] - v[n] }/S

Each sub-block requires n+2 bytes so the longest sub-block uses 27 bytes. If each sensor has 1000 blocks then it will require 50 sub-blocks, each with 27 bytes. 8 sub-blocks will fit into each message (189/22) so 7 messages are needed per sensor. The total bytes then is 50*22 +7*16 which equals 1212. Thus a CTD profile with 1000 blocks can be sent in 3*1212 = 3636 bytes.

2. Curvature Packing (New to V2.0 and later)

The packing routine is introduced to reduce the volume of transmitted data, primarily by allowing for variation in the bytes alloted for the data. The bytes alloted will be constant within a 16 value sub-block, but will differ between parameters and between sub-blocks of the same parameter.

IDjjBNNVVVDDDpppppppppppppsub-block 0><sub-block 1> . . . <sub-block sb>;

- **ID** = one-byte sensor ID code and index. The low order hex digit is the message index for this sensor. For example, the pressure messages would have ID's:10,11,12... and message index (m) of 0, 1, 2, ...
- jj = Profile Packing Format (MS nibble)/Number of bytes for this message (LS 3 nibbles). Profile Packing Format = 0 for Legacy Diff. (backwards compatible), 1 for Curv. Number of bytes count includes ID, jj, the data, and the trailing;.
- B = count of first sub-block number in message, as 1 byte. For message index, m =0, B=0, for succeeding messages m > 0, B > 0. The position (n) of the first value recorded in a message (VVV) can be computed as TopIndx = m + B * 16, where m is the message index.

NN = total number of values given in the message as 2 bytes.

- VVV = v[n=TopIndx] first value as 3 binary bytes. In all messages greater than 1, VVV will be the same value as the last value packed in the previous message. Said another way, there is an overlap of 1 value between messages. This allows an additional check on the validity of the data transmitted.
- DDD = {v[n=TopIndx+1] v[n=TopIndx]} first-differenced, second value as 3 bytes. pppppppppppp = (12 bytes) packing factors for the sub-block second differences where each 3 bits indicate the dynamic range for each sub-block. The packing factor will be the number of nibbles needed to represent the dynamic range of the variable. For example, if the range is from 7 to -7, then the value can be expressed unambiguously using 1 nibble and the packing factor would be 1. Using 12 bytes for the packing factors, there can be up to 32 sub-blocks, or 512 values if the packing factor is 1 (1 nibble). Unfilled factors are valued at 0.

<sub-block i> = { v[n+2+i*16] - 2*v[n+1+i*16] + v[n+i*16] } where n=0,..,15 and i=1,..,sb =number of sub-blocks.

Each non-last sub-block (i=1:sb-1) will have 16 values in it and will have a total length of of 8 to 32 bytes. The last sub-block (i=sb) will have between 1 and 16 values and a length between 1 and 32 bytes. Message index m > 1 (example ID=11) overlap the previous message index m-1 by 1 value. Thus the VVV value in message index m will be redundant with the last value from message index m-1. If all sub-blocks are full in message index m, then the message contains values for index n = m + B * 16 through n = 1 + m + (B + sb_m) * 16, where sb_m is be the number of sub-blocks in the message m.

Suppose sub-block i has n values v[2+i*16], v[3+i*16],...v[n+2+i*16], and the packing factor = 2 Then this sub-block will be transmitted as:

Sub-block Byte	Contents
0	v[2+i*16] – 2*v[1+i*16] + v[i*16]
1	v[3+i*16] – 2*v[2+i*16] + v[1+i*16]
Π	v[n+2+i*16] – 2*v[n+1+i*16] + v[n+i*16]

Within a message, the original values can then be reconstructed by (1) starting with DDD and doing a cumulative sum of the entries for the sub- blocks, and then (2) using these values and starting with VVV doing a second cumulative sum.

Missing Data

The profile series will have gaps in it if there is no valid CTD data in a block. In that case, all of the profile series will be missing the same gap. If a block average contains no valid data, that block is ignored and is not transmitted. For example, suppose the pressure bin size is 1 db and that bin 0 has P=0. Suppose there is no valid data in bin 5. Then the sub-block will contain:

Note that the 6th bin, for which P=5, will be omitted from the pressure, temperature, and salinity messages.

Converting to scientific Units

After the sub blocks have been reassembled into a sequence of observations, the counts are converted to scientific units by:

```
dBar = pressure counts *Pgain - Poff
degC = temperature counts *Tgain - Toff
psu = salinity counts *Sgain - Soff
```

The values of Gain/Offset are now sent back within the Argo Metafile message (0xf0) for data decoding purposes allowing a way to determine what Gain/offset is used in a given cycle. The GAIN/OFFSET of Temperature/Salinity/Pressure can be modified via 2-way communication. Modifying these parameters will effect all variables returned.

High Resolution Pressure data (ID=0x9n, n=0:7)
High Resolution Temperature data (ID=0xan, n=0:7)
High Resolution Salinity data (ID=0xbn, n=0:7)

The float can be set to return a high resolution P,T,S profile spanning a subsection of the primary binned profile. Data is packed and decoded similarly to the binned profile (ID=0x1n, 0x2n, 0x3n). The High Resolution profile can return every scan of the CTD (1 Hz) or every other scan (1/2 Hz). The data is limited to 1024 values. [Note: Prior to firmware 11Dec15, to return the High Resolution data, the averaging of the primary binned profile must be done by the float (not within the CTD). With firmware 11Dec15 and after, either the CTD or the float can bin the data. Typical SOLO II averging uses every other CTD scan. However if the High Resolution profile includes every scan, the bin averages will also use every scan. Thus the averaging of the primary binned profile may differ between the subsection with High Resolution data and all other spans. High Resolution profile data is decoupled from BinMod and is set to always use 'curvature packing'.

<u>Drift Pressure timeseries data (ID=0x9n, n=8:f)</u>
<u>Drift Temperature timeseries data (ID=0xan, n=8:f)</u>
<u>Drift Salinity timeseries data (ID=0xbn, n=8:f)</u>

The float can be set to return a timeseries of P,T,S recorded during the drift phase. Data is packed and decoded similarly to the binned profile (ID=0x1n, 0x2n, 0x3n), thus no time information is returned. Time can be estimated from the rise/fall records and the sampling interval of the drift data. The first value is taken a few seconds after drift begins, while the last value is taken a few seconds before drift ends. Thus there should be NsamX+1 values. The data is limited to 1024 values. Drift data is decoupled from BinMod and is set to always use 'curvature packing'.

Fall Rate data (ID=0x4n)

As it falls from the surface to its drift depth, SOLOII periodically interrogates the SeaBird for a depth reading. This time series is sent back in this data message.

The data message looks like:

```
IDij<start time><time(1),depth(1)> . . . <time(m),depth(m)>;
        ID = one-byte sensor ID code = 0x4n.
         ii = Fall Packing Format (MS nibble)/Number of bytes in the message (LS 3
               nibbles). Fall Packing Format = 0 for Legacy 4 byte reporting (backwards
               compatible), 1 for 5 byte reporting. The count includes ID, ii, the data, and the
               trailing:.
 start time = SOLO time at start of message (seconds since 1Jan2000) in 4 bytes (MSB
               first). This will be start of Fall in ID=0x40.
    time(i) = seconds since start time in 2 bytes, i=1, ..., m.
    code(i) = Code representing float phase while data value recorded in 1 nibble, i=1, ..., m.
               Possible Phase codes values
                       START OF SINK
                                                                =1,
                       Buoyancy at 100db
                                                                =2.
                       SEEK
                                                                =3,
                       BEGINNING OF DRIFT
                                                                =4.
                       SEEK DURING DRIFT
                                                                =5.
                       BEGINNING OF FALL TO PROFILE
                                                                =6,
                       START OF RISE
                                                                =7.
                       END OF RISE
                                                                =8.
                       ICE TURNAROUND
                                                                =9,
                       SINKING
                                                               =10.
                       DRIFTING
                                                               =11.
                       FALLING TO PROFILE
                                                               =12,
                       RISING
                                                               =13.
                       SURFACE
                                                               =14:
   depth(i) = depth (LSB=Pgain db) at time(i) in 2.5 bytes, i=1, ..., m.
               dBar = Pgain * depth(i) - Poff
               depth(i) = 0xffff if the pressure reading is invalid
```

Each depth observation takes 5 bytes. The first time is taken when the valve is opened to leave the surface. The next two times are when the float passes 50m and 100m. After 100 m, pressures are logged every 30 minutes. Typically we allow for 500 (**Falin**) minutes for the SOLOII to fall 1000 meters so there will be about 16 more measurements. The last record should be recorded when the float begins its park phase.

Fall Rate data can be found over multiple messages.

The float resets its clock using GPS typically, but can use Iridium time if GPS is unavailable. Any re-epoch of the Iridium system will shift the reported time (after reset by Iridium) by 226492400 seconds.

Maximum of 240 Fall values can be transmitted in a given cycle.

Rise Rate data (ID=0x5n)

The rise rate message is identical in structure to the fall rate message. The rise rate time series begins when the SOLO II opens its valve to descent from the drift depth to the profile depth. It logs a pressure/time record 10 times during its descent to the profile depth (interval = **PwaitN**/10). At the bottom of dive, whether determined by timing out (exceeding **PwaitN**) or by reaching the target depth (**ZproN**), another pressure/time record is logged. At this point, the float pumps for **PmpBtm** seconds. A pressure/time record is logged every 30 minutes while the float is ascending. An additional Rise Rate record has been introduced in V2.0 which is measured AFTER surface buoyancy pumping.

Rise Rate data can be found over multiple messages.

Note: There is a bug in the rise record data, when the ice-estimation routine is tripped. The bug leads to there being multiple code=9 (Ice Turnaround), in the rise record. The first code=9 is valid, the rest are not.

Maximum of 240 Fall values can be transmitted in a given cycle.

Pump data (ID=0x6n)

The data message looks like:

```
IDij < depth(1), time(1), voltage(1), current(1), vac0(1), vac1(1) > ...
   < depth(m).time(m).voltage(m).current(m).vac0(m).vac1(m);
        ID = one-byte sensor ID code = 0x6n.
         ij = Pump Packing Format (MS nibble)/Number of bytes in the message (LS 3
               nibbles). Pump Packing Format = 0 for Legacy 10 byte packing (backwards
               compatible), 1 for 11 byte packing. The count includes ID, ji, the data, and the
               trailing:.
    code(i) = Code representing float phase in 1 nibble, i=1, ..., m (See Fall for values).
   depth(i) = depth (LSB=Pgain db) at time(i) in 2.5 bytes, i=1, ..., m.
               dBar = Pgain * depth(i) -Poff
               depth(i) = 0xffff if the pressure reading is invalid
    time(i) = seconds the pump ran in 2 bytes (signed)
  voltagei) = average pump battery counts while pumping in 2 bytes (0.01V)
  current(i) = average pump current at bottom in 2 bytes, LSB=1ma
    vac0(i) = vacuum counts after pump starts in 1 byte
    vac1(i) = vacuum counts before pump stops in 1 byte
```

Pump time series can be found over multiple messages.

The pump time series typically reports the pressure prior to pumping. However in the last pump record (Code=14), the pressure reported is post pumping.

Engineering data (ID=0xe0, 0xe2, 0xe3, 0xe5, 0xe6)

The engineering data is used to diagnose SOLOII anomalies. A different format is used in each of the 3 distinct phases of a SOLOII mission. The LS nibble of the ID indicates the phase of the mission.

ID=0xe0, Engineering message in 1st diagnostic dive at start of mission Byte Contents

Mission EEPROM dump (ID=0xdn)

Byte	Contents
0	ID/Mission phase = 0xd0,0xd1,0xd2,0xd3 [Possible values 0:d]
1-2	len=Number of bytes (variable, see below)
3- (len-2)	ASCII listing of mission parameters
	Each EEPROM parameter has a 6 character name and 5 char value: NAMExx=vvvvvv
	The = & signs are present in the listing of each parameter. (15 bytes/parameter)
	Successive parameters follow without gaps.
len-1	; terminator at the end of the dump

An example showing only the initial 3 and final 2 elements follows: **PROup = 1| BLOK=** 1| **PB1=** 10|...| **XP2=** 0| **XPdly=** 0|;

The EEPROM dump message is sent only in response to a command "**P**" from the ground station. It is sent over 4 SBD messages (0xd0=328 bytes, 0xd1=328 bytes, 0xd2=328 bytes, 0xd3=46 bytes.

Float Echo (ID=0xde)

Byte	Contents
0	ID/Mission phase = 0xde
1-2	len=Number of bytes (includes ID and ;)
3- (len-2)	ASCII string
len-1	; terminator at the end of the echo

Float responds to commands. Within the Echo, the returned ascii string is followed by a ':' if the command was NOT accepted by the float. and if followed by a ';' then the command was accepted and should change float behavor.

Argo Data ID=0xf0 Relayed in normal cycles

Byte	Contents
0	ID/Mission phase = 0xf0
1-2	Number of bytes = $37 = 0x25$
3	Data Version (Minor version in high order nibble, major version in low order)
4-5	Target profile depth
6-7	Target parking depth
8-9	Maximum rise time in minutes
10-11	Target (maximum) fall to parking depth time in minutes
12-13	Maximum fall-from-parking-to-profile-depth time in second
14-15	Target drift time (units=5 minutes; To convert to minutes multiply packed value by 5)
16	Float version (0 SOLOII)
17	Target ascent rate while profiling
18-19	Number of seeks
20-21	Surface Time
22-23	Seek Interval in minutes
24-25	Pressure scaling gain; db=counts/gain-offset
26-27	Pressure scaling offset
28-29	Temperature scaling gain; degreesC=counts/gain-offset
30-31	Temperature scaling offset
32-33	Salinity scaling gain; PSU=counts/gain-offset
34-35	Salinity scaling offset
36	; terminator

The values of Gain/Offset are now sent back within the Argo Metafile message (0xf0) for data decoding purposes allowing a way to determine what Gain/offset is used in a given cycle. The GAIN/OFFSET of Temperature/Salinity/Pressure can be modified via 2-way communcation. Modifying these parameters will effect all variables returned.

Float Version= SOLOII/S2A 0; Deep SOLO/S2A 1; ALAMO 3

Test Data (ID=0xf1)

Буце	Contents
0	ID/Mission phase = 0xf1
1-2	Number of bytes = variable
